An often used way to obtain networks is the *computer-assisted text analysis* (CaTA). *Terms* considered in TA are collected in a *dictionary* (it can be fixed in advance, or built dynamically). The main two problems with terms are

- *equivalence* – different words representing the same term, and
- *ambiguity* – same word representing different terms.

Because of these the *coding* – transformation of raw text data into formal *description* – is done often manually or semiautomatically.

We assume that unit identification (entity recognition) assigns a unique identifier (ID) to each unit. For some types of units, such IDs are standardized: ISO 3166-1 alpha-2 two-letter country codes, ISO 9362 Bank Identifier Codes (BIC), ORCID Open Researcher and Contributor ID, ISSN International Standard Serial Number, DOI Digital Object Identifier, URI Uniform Resource Identifier, etc. In data displays, often IDs are replaced by corresponding (short) labels/names.

Graphs and
networks

Types of
networks

Knowledge
graphs

Network
formats

Network
description

Nets and
NetsJSON

Elements

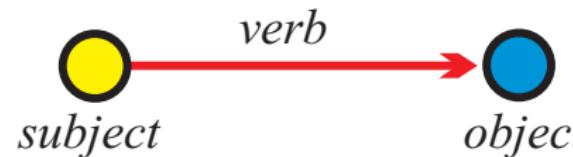

Conclusions

References

As *units* of TA we usually consider clauses, statements, paragraphs, news, messages, ...

In thematic TA the units are coded as rectangular matrix
Text units \times *Concepts* which can be considered as a two-mode network.

In semantic TA the units (often clauses) are encoded according to the S-V-O (*Subject-Verb-Object*) model or its improvements.

This coding can be directly considered as network with *Subjects* \cup *Objects* as nodes and links (arcs) labeled with *Verbs*.

Analyse von Snoopy Comics

A **network** is based on two sets – set of **nodes** (vertices), that represent the selected **units**, and set of **links** (lines), that represent **ties** between units. They determine a **graph**. A link can be **directed** – an **arc**, or **undirected** – an **edge**. Additional data about nodes or links can be known – their **properties** (attributes). For example: name/label, type, value, ...

Network = Graph + Data

The data can be measured or computed.

A **network** $\mathcal{N} = (\mathcal{V}, \mathcal{L}, \mathcal{P}, \mathcal{W})$ consists of:

- a **graph** $\mathcal{G} = (\mathcal{V}, \mathcal{L})$, where \mathcal{V} is the set of nodes, \mathcal{A} is the set of arcs, \mathcal{E} is the set of edges, and $\mathcal{L} = \mathcal{E} \cup \mathcal{A}$ is the set of links.
 $n = |\mathcal{V}|$, $m = |\mathcal{L}|$
- \mathcal{P} **node value functions** / properties: $p : \mathcal{V} \rightarrow A$
- \mathcal{W} **link value functions** / weights: $w : \mathcal{L} \rightarrow B$

Additional information/data about values:

- How can we compute with values – algebraic structures semigroup, monoid, group, semiring, etc.
- Properties of values – in a molecular graph an atom is assigned to each node; properties of relevant atoms are such additional data.

Conclusions

References

Besides ordinary (directed, undirected, mixed) networks some extended types of networks are also used:

- *2-mode networks*, bipartite (valued) graphs – networks between two disjoint sets of nodes.
- *multi-relational networks*.
- *linked networks* and *collections of networks*.
- *temporal networks*, dynamic graphs – networks changing over time.
- specialized networks: representation of genealogies as *p-graphs*; *Petri's nets*, ...

The network (input) file formats should provide means to express all these types of networks. All interesting data should be recorded (respecting privacy).

Two-mode networks

Network description

Nets and NetsJSON

Elements

Conclusions

References

In a **two-mode** network $\mathcal{N} = ((\mathcal{U}, \mathcal{V}), \mathcal{L}, \mathcal{P}, \mathcal{W})$ the set of nodes consists of two disjoint sets of nodes \mathcal{U} and \mathcal{V} , and all the links from \mathcal{L} have one endnode in \mathcal{U} and the other in \mathcal{V} . Often also a **weight** $w : \mathcal{L} \rightarrow \mathbb{R} \in \mathcal{W}$ is given; if not, we assume $w(u, v) = 1$ for all $(u, v) \in \mathcal{L}$.

A two-mode network can also be described by a rectangular matrix $\mathbf{A} = [a_{uv}]_{\mathcal{U} \times \mathcal{V}}$.

$$a_{uv} = \begin{cases} w_{uv} & (u, v) \in \mathcal{L} \\ 0 & \text{otherwise} \end{cases}$$

Examples: (persons, societies, years of membership),
(buyers/consumers, goods, quantity), (parliamentarians, problems,
positive vote), (persons, journals, reading).

Knowledge graphs

Network formats

Network description

Nets and NetsJSON

Elements

Conclusions

References

A *multi-relational network* is denoted by

$$\mathcal{N} = (\mathcal{V}, (\mathcal{L}_1, \mathcal{L}_2, \dots, \mathcal{L}_k), \mathcal{P}, \mathcal{W})$$

and contains different relations \mathcal{L}_i (sets of links) over the same set of nodes. Also the weights from \mathcal{W} are defined on different relations or their union.

Examples of such networks are: Transportation system in a city (stations, lines); **WordNet** (words, semantic relations: synonymy, antonymy, hyponymy, meronymy, ...), **KEDS** networks (states, relations between states: Visit, Ask information, Warn, Expel person, ...), ...

Linked networks and collections of networks

In a *linked* or *multimodal* network

$$\mathcal{N} = ((\mathcal{V}_1, \mathcal{V}_2, \dots, \mathcal{V}_j), (\mathcal{L}_1, \mathcal{L}_2, \dots, \mathcal{L}_k), \mathcal{P}, \mathcal{W})$$

the set of nodes \mathcal{V} is partitioned into subsets (*modes*) \mathcal{V}_i , $\mathcal{L}_s \subseteq \mathcal{V}_p \times \mathcal{V}_q$, and properties and weights are usually partial functions.

A set of networks $\{\mathcal{N}_1, \mathcal{N}_2, \dots, \mathcal{N}_k\}$ in which each network shares a set of nodes with some other network is called a *collection* of networks.

Bibliographical information is usually represented as a collection of bibliographical networks $\{WA, Cite, WK, WC, WI, \dots\}$.

A *multilevel network* organizes nodes into hierarchical levels, where each level represents a different scale or granularity of interaction or connectivity. It is a special case of a linked network.

Key characteristics of multilevel networks are: hierarchical levels, inter-level links, scale-specific dynamics, and modularity.

Each level may have its unique dynamics, rules, or behaviors. For example, in a biological network, one level might represent protein-protein interactions, while another level represents cellular interactions. They often exhibit modularity, where nodes within a level are more densely linked to each other than to nodes in other levels. This modularity can help in understanding the functional or structural organization of the network.

Example: a multilevel network in the context of a university: Level 1: Individual students and faculty members. Level 2: Departments or academic units. Level 3: The entire university.

In a *temporal network* the presence/activity of node/link can change through time.

Temporal network

$$\mathcal{N}_T = (\mathcal{V}, \mathcal{L}, \mathcal{P}, \mathcal{W}, T)$$

is obtained if the *time* T is attached to an ordinary network. T is a set of *time points* $t \in T$.

In temporal network nodes $v \in \mathcal{V}$ and links $l \in \mathcal{L}$ are not necessarily present or active in all time points. If a link $l(u, v)$ is active in time point t then also its endnodes u and v should be active in time t .

We will denote the network consisting of links and nodes active in time $t \in T$ by $\mathcal{N}(t)$ and call it a *time slice* in time point t .

Pajek supports two types of descriptions of temporal networks based on *presence* and on *events*.

We introduce a notion of a *temporal quantity*

$$a(t) = \begin{cases} a'(t) & t \in T_a \\ \text{\#} & t \in \mathcal{T} \setminus T_a \end{cases}$$

where T_a is the *activity time set* of a and $a'(t)$ is the value of a in an instant $t \in T_a$, and \# denotes the value *undefined*.

We assume that the values of temporal quantities belong to a set A which is a *semiring* $(A, +, \cdot, 0, 1)$ for binary operations $+ : A \times A \rightarrow A$ and $\cdot : A \times A \rightarrow A$.

Let $A_{\text{\#}}(\mathcal{T})$ denote the set of all temporal quantities over $A_{\text{\#}}$ in time \mathcal{T} . To extend the operations to networks and their matrices we first define the *sum* (parallel links) $a + b$ as

$$(a + b)(t) = a(t) + b(t) \quad \text{and} \quad T_{a+b} = T_a \cup T_b.$$

The *product* (sequential links) $a \cdot b$ is defined as

$$(a \cdot b)(t) = a(t) \cdot b(t) \quad \text{and} \quad T_{a \cdot b} = T_a \cap T_b.$$

Network
description

Nets and
NetsJSON

Elements

Conclusions

References

Let us define TQs **0** and **1** with requirements $\mathbf{0}(t) = \text{\texttt{#}}$ and $\mathbf{1}(t) = 1$ for all $t \in \mathcal{T}$. Again, the structure $(A_{\text{\texttt{#}}}(\mathcal{T}), +, \cdot, \mathbf{0}, \mathbf{1})$ is a semiring.

To produce a software support for computation with TQs we limit it to TQs that can be described as a sequence of disjoint time intervals with a constant value

$$a = [(s_i, f_i, v_i)]_{i \in 1..k}$$

where s_i is the starting time and f_i the finishing time of the i -th time interval $[s_i, f_i]$, $s_i < f_i$ and $f_i \leq s_{i+1}$, and v_i is the value of a on this interval (over combinatorial semiring). Outside the intervals the value of TQ a is undefined, $\text{\texttt{#}}$.

For example

$$a = [(1, 5, 2), (6, 8, 1), (11, 12, 3), (14, 16, 2), (17, 18, 5), (19, 20, 1)]$$

In a temporal network some node properties and/or link weights are assigning TQs.

Network description

Nets and NetsJSON

Elements

Conclusions

References

A knowledge graph is a structured representation of knowledge that captures entities, relationships, and attributes in a graph-based format. New entities, relationships, and attributes can be added dynamically. Knowledge graphs have evolved from early semantic networks (1960s) and ontologies to become powerful tools for representing and reasoning about complex knowledge. The Austrian linguist Edgar W. Schneider coined the term "knowledge graph" in 1972..

A knowledge graph is a graph of data intended to accumulate and convey knowledge of the real world, whose nodes represent entities of interest and whose edges represent potentially different relations between these entities [1].

A knowledge graph acquires and integrates information into an ontology and applies a reasoner to derive new knowledge [2].

Network
description

Nets and
NetsJSON

Elements

Conclusions

References

Knowledge graphs are widely used in applications like semantic search, recommendation systems, natural language processing, and artificial intelligence. They are often built using standards like RDF (Resource Description Framework) and queried using languages like SPARQL.

There is no generally accepted definition of a knowledge graph. Most approaches are based on a set of *facts* \mathcal{F} , where each fact is a triple of the form (e_1, r, e_2) or (e, a, v) , with: $e, e_1, e_2 \in E$, $r \in R$, $a \in A$, and v (value, which can be a literal or another entity). E is a set of *entities* (nodes), representing real-world objects, concepts, or instances. R is a set of *relationships* (arcs), representing directed links between entities. A is a set of *attributes*, representing properties or characteristics of entities or relationships.

... Knowledge graphs formally

The set of facts \mathcal{F} can be represented with a *knowledge graph* (network)

$$G = (\mathcal{V}, \mathcal{A}, \lambda)$$

such that for every arc $\ell(u, v) \in \mathcal{A}$ the triple $(\lambda(u), \lambda(\ell), \lambda(v)) \in \mathcal{F}$ and there is an arc in \mathcal{A} for each triple from \mathcal{F} . There is no isolated node in \mathcal{V} . The function $\lambda : \mathcal{V} \cup \mathcal{A} \rightarrow \mathcal{L}$ where \mathcal{L} is a set of *labels*, provides semantic meaning to entities, relationships, and attributes.

In a network, the labels on nodes are considered standard node property; arcs with the same label determine the corresponding relation. Therefore the knowledge graph G is a multi-relational network. Usually, the attribute arcs and attribute value nodes are transformed into functions (node properties).

Nets and
NetsJSON

Elements

Conclusions

References

An S-V-O triple on which the knowledge graph is based corresponds in logic to a binary predicate $V(S, O)$. In sentences describing facts predicates of larger -arity can appear. For example ***

An approach would be to use hypergraphs instead of graphs.

Another approach is to express k-ary predicate as a binary predicate. Consider a 4-ary predicate $P(x, y, t, z)$. The quadruple (x, y, t, z) can be expressed as a pair in three ways $(x, (y, t, z))$, $(x, y), (t, z)$, and $((x, y, t), z)$. Defining a binary predicate $P'(x, (y, t, z)) = P(x, y, t, z)$ we get the triple $(x, P', (y, t, z))$.

Reification in knowledge representation is the process of turning a predicate or statement into an addressable object. Reification allows the representation of assertions so that they can be referred to or qualified by other assertions **WP**.

Conclusions

References

In 2023, the International Network for Social Network Analysis (INSNA) requested that Zachary Neal form a working group to develop **recommendations for sharing network data and materials**. They were published in *Network Science* in 2024 [3] accompanied with the *Endorsement page* [4].

It would be useful to have a common “archiving/intermediate” format that can describe (almost) all networks. It is easy to write converters from this format to a selected format or corresponding network reading procedures.

There are many tools and programs for network analysis UCINET, Pajek, Gephi, NetMiner, Cytoscape, NodeXL, E-Net, Tulip, PUCK, GraphViz, SocNetV, Kumu, Polinode, etc.

They are supporting different network description formats: CSV, UCINET DL, Pajek NET, Gephi GEXF, GDF, GML, GraphML, GraphViz DOT, Tulip TPL, Netdraw VNA, Spreadsheet, etc. [5].

In addition, network data appears in several application areas such as chemistry and genealogy. There are many formats for describing molecular graphs: Molfile, SDF, CML, PDB, XYZ, CIF, FASTA, CDX, CDXML, JCAMP-DX, SMILES, InChI, and others. The most widely used format for genealogical data exchange, GEDCOM is a plain text file format that stores information about individuals, families, events, and sources. It has several derivatives. It is considered an exchange format between various genealogy programs, which are often based on their own format. Some of the most well-known are Ancestry Tree Files, Family Tree Maker, Legacy Family Tree, RootsMagic, OpenGen Alliance, Open Archives Format, FamilySearch JSON, Gramps XML, TEI, PROGEN, Webtrees, PAF.

There are three commonly used file representations of graphs and networks.

- **Link list (with weights)** This is the most commonly used and expressively most flexible representation.
- **Matrix representation** It is often found in older sources. It is suitable for describing smaller, denser simple networks. We lose the distinction between directed and undirected and multiple links. For larger networks, which are usually sparse, it requires a lot of space – most matrix entries have the value 0.
- **Neighbor sets** This representation is very economical but only useful for networks without link properties.

How to describe a network $\mathcal{N} = (\mathcal{V}, \mathcal{L}, \mathcal{P}, \mathcal{W})$? In principle the answer is simple – we list its components \mathcal{V} , \mathcal{L} , \mathcal{P} , and \mathcal{W} . The simplest way is to describe a network \mathcal{N} by providing $(\mathcal{V}, \mathcal{P})$ and $(\mathcal{L}, \mathcal{W})$ in a form of two tables.

As an example, let us describe a part of the network determined by the bibliographical data about the following works: **Generalized blockmodeling**, **Clustering with relational constraint**, **Partitioning signed social networks**, **The Strength of Weak Ties**.

There are nodes of different types (modes): persons, papers, books, series, journals, publishers; and different relations among them: author_of, editor_of, contained_in, cites, published_by. For some types of nodes additional properties are known: sex, year, volume, number, first and last page, etc.

Both tables are often maintained in Excel. They can be exported as text in **CSV** (Comma Separated Values) format.

To save space and improve computing efficiency we often replace values of categorical variables with integers. In R this encoding is called a *factorization*.

We enumerate all possible values of a given categorical variable (coding table) and afterward replace each value with the corresponding index in the coding table. Since node labels/IDs can be considered a categorical variable, factorization is usually applied also on them.

This approach is used in most programs dealing with large networks. Unfortunately, the coding table is often considered as a kind of meta-data and is omitted from the description.

Be careful, in data analysis, indices start with 1, but real computer scientists start counting from 0.

Using a short program in R we transform both tables into Pajek files: a network file `bib.net` and partition files `bibMode.clu` and `bibSex.clu`. All the files related to the bibliographic example are available at GitHub/Bavla [6].

We were satisfied with the "traditional" network description until we became interested in networks with node/link properties that are not measured in standard scales (ratio, interval, ordinal, nominal), but have structured values (text, subset, interval, distribution, time series, temporal quantity, function, etc.). For describing temporal networks we initially, extending the Pajek format, defined and used the Ianus format [7].

We needed a format that could describe structured values. We could base our format on two options – XML and JSON. We chose JSON and in 2015 started developing the NetJSON format and the Nets Python package to handle networks with structured-valued properties [8–10].

Network
description

Nets and
NetsJSON

Elements

Conclusions

References

On February 26, 2019, the format was renamed to NetsJSON because of the collision with <http://netjson.org/rfc.html>. NetsJSON has two versions: a *basic* and a *general* version. The current implementation of the Nets library supports only the basic version.

In addition to describing networks with structured values, NetsJSON is expected to offer the capabilities of (most) existing network description formats [11] (archiving, conversion) and provide input data for D3.js visualizations.

An event description can contain fields:

```
{ "date": date,  
  "title": short description,  
  "author": name,  
  "desc": long description,  
  "url": URL,  
  "cite": reference,  
  "copy": copyright  
}
```

It is intended to provide information about the "life" of the dataset – changes, releases, uses, publications, etc.

For describing temporal networks a node element and a link element have an additional required property tq – a temporal quantity.

For an example see GitHub/Bavla/Graph/JSON/violenceU.json describing Franzosi's violence network.

The general NetsJSON format is also expected to support the description of network collections.

In recent years we also analyzed bike systems (link weight is a daily number of trips distribution), bibliographies (yearly distributions of publications or citations), and multiway networks [12–14]. It turned out that it was necessary to add another main field, data, to the basic NetsJSON format, in which we provide additional data about the properties of values (translations of labels in selected languages, algebraic structure [15]).

Graphs and networks

Types of networks

Knowledge graphs

Network formats

Network description

Nets and NetsJSON

Elements

Conclusions

References

Our experience with network analysis to date is summarized in the following recommendations on the elements of a common format for describing networks.

For data integrity, it makes sense to combine data and metadata into a single file. To preserve the structure of data, it makes sense to base the format on JSON, which fits well with the data structures of modern programming languages.

We would also encourage the provision, as metadata, of information about the context of the network, additional knowledge about it, articles or notebooks on its analysis, comments of users, etc. Kaggle is a good example. An improved ICON repository or Networkrepository (we disagree with their "citation request") could be the way to go. Existing metadata standards should be taken into account ([Dublin Core](#), [FAIR](#), [Schema](#)). Data has a "life". When selecting data, its age is often important. Metadata should include at least the creation date and the last modification date.

... Elements of a common network format

Network format

V. Batagelj et al.

Graphs and networks

Types of networks

Knowledge graphs

Network formats

Network description

Nets and NetsJSON

Elements

Conclusions

References

The format must support all types of networks (simple, 2-mode, linked, multi-relational, multi-level, temporal). The network can contain both arcs and edges, as well as parallel links.

As mentioned earlier, using factorization produces a more concise description of the network. In cases where the node names are not too long and are readable, we sometimes want to avoid factorization. This can be achieved by using a switch that indicates whether factorization is used. We can also shorten the description length by introducing default values. If we also allow counting from 0, it makes sense to add information about the smallest index.

Long labels cause problems when printing/visualizing (parts of) networks and results. Therefore, it is useful to have abbreviated versions of labels available.

Graphs and networks

Types of networks

Knowledge graphs

Network formats

Network description

Nets and NetsJSON

Elements

Conclusions

References

Most of the network datasets produced by network science have no node labels. Node labels are not needed if you study distributions, but they are very important in the interpretation of the obtained “important substructures”. We would encourage providing node labels, or at least some typology info in the case of privacy issues.

Operations and transformations on networks: extensions (new yearly data), constructive description (, NetML [16]), intersection, union, ... product; derived networks .

We have not yet started working on a general format. It is supposed to enable descriptions of collections of networks. The question arises about the scope of validity of IDs - does the same ID in different networks represent the same or different units? This is important for operations such as union or intersection of networks. Which way to go - introducing contexts or using matchings?

The availability of the data used in the article enables the reproducibility and verifiability of the analyses performed. In addition, the obtained results can be verified or supplemented with other methods. When developing new methods, accessible and well-documented data are also very important - it is good to test a new method on several data sets and check whether it gives meaningful/expected results.
